PARAMETRIC-METRIC

Parametric methods make strong assumptions about the form or structure of the function that relates the input and the output ($f: X \rightarrow Y$). In other words, they assume the data follows a certain distribution or pattern.

Unlike parametric methods, non-parametric methods do **not** make strong assumptions about the form of the function that connects the inputs and outputs. They are more flexible and can adapt to various data structures.

PARAMETRIC VS NON-PARAMETRIC MODELS

Parametric methods make strong assumptions about the form or structure of the function that relates the input and the output ($f: X \rightarrow Y$). In other words, they assume the data follows a certain distribution or pattern.

Unlike parametric methods, non-parametric methods do not make strong assumptions about the form of the function that connects the inputs and outputs. They are more flexible and can adapt to various data structures.

PARAMETRIC VS NON-PARAMETRIC MODELS

Example

Scenario: Imagine we have a dataset of different countries. For each country, we have information on GDP, education level, access to clean water, and vaccination rates. We also have the average life expectancy for each country.

Goal: For a new country (or a region within a country) with known GDP, education level, access to clean water, and vaccination rates, we want to predict the life expectancy (Continuous or Discrete).
